The antisense compounds are useful for inhibiting the expression of human cells or tissues. They are also useful for modulating the expression of Akt.3, and for treating a human or an animal suspected of having, or being prone to, a disease or condition associated with Akt.3 expression. The antisense compounds may also be used as research reagents, in kits and in diagnostics, e.g. to elucidate the function of a particular gene or to distinguish between functions of various members of a biological pathway; and as a prophylactic, e.g. to prevent or delay infection, inflammation or tumour formation.
The present sequence is a primer used to isolate human Akt-3 cDNA from human brain cDNA by 3' rapid amplification of cDNA ends (3' RACE). Akt-3 is a third human isoform of Akt, which is also known as protein kinase B (PKB) or "related to A and C protein kinase" (RAC-PK). It is located on human chromosome 1, region q43-q44. The present primer was used in the second round of 3' RACE. The sequence is based on the product of the first round, which was performed using primers based on a human hippocampal EST sequence that showed high similarity to the rat RAC-PKgamma sequence. Primers based on the product of the second round of 3' RACE were then used to amplify the complete coding sequence of Akt-3
                                                                                                                                                                                                                                 New human serine/threonine kinase protein and the polynucleotide encoding the protein, useful for preparing a medicament for treating disorders associated with human serine/threonine kinase protein
                                                                                                                                                                                      Disclosure;

sequence of Akt-3

of naturally occurring nucleobases covalently bound to a polyamide backbone and (b) hybridise to the translation initiation AUG region, coding region, 5' untranslated region (5' UTR) or 3' untranslated region (5' UTR) of PKC-alpha or its isoforms. The PNAs can be used to target RNA and single stranded DNA (ssDNA) to produce antisense-type gene

peptide nucleic acid (PNA) oligomers are provided which (a) naturally occurring nucleobases covalently bound to a polyami

consist

Agents which influence the activity of Akt-3 protein, and so stimulate apoptosis, may also be used to treat diseases associated with Akt-3.
                                                                                                                                                                                                                                                                                                                                                                        misc_feature

The sequences given in AAQ84236-40 are oligos which are antisense to the protein kinase C-epsilon (PKC-epsilon) CDNA. These antisense molecules may be used in modulating the expression of this particular isozyme of PKC. The oligos of the invention preferably hybridise with the 5'- or 3'-untranslated regions of the PKC gene, or the translation initiation site, or the coding region. These oligos may be used in the detection of the human PKC genes and for treatment of animals with conditions associated with PKC, esp. hyperproliferative diseases such as psoriasis.
                                                                                                                                                                          Oligo:nucleotide(s) hybridisable with Protein Kinase C m gene - also novel PKC-alpha 3'-UTR sequence, useful for diagnosis and treatment of hyperprolliferative disorders.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Antisense; protein kinase C; alpha; PKC; beta; gamma; eta; epsil zeta; modulation; expression; isozyme; hybridise; 5' UTR; human; 3' untranslated region; translation initiation site; detection; phosphorothicate linkage; 2'-O-methyl modification; 2'-O-propyl modification; ss.
                                                                                                                                                                                                                                                WPI;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     They are also able to form triple helices in which a first PNA strand binds with RNA or ssDNA and a second PNA strand binds with the resulting double helix or with the first PNA strand. The PNAs possess no significant charge and are water soluble, which facilitates cellular uptake. Further, since they contain amides of non-biological amino acids, they are biostable and resistant to enzymatic degradation by proteases. The present sequence targets the coding region of PKC-epsilon.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   regulation moleties. They inhibit expression of PKC-alpha and its isoforms (including beta, gamma, delta, epsilon, zeta and eta) are useful for treating and diagnosing cell proliferation and differentiation processes such as neoplastic, hyperproliferative

                                                                                                                                        The present invention describes antisense oligonucleotides up to 50 nucleotides in length which specifically bind mRNA encoding human protein kinase C (PKC). AAZ27266 to AAZ27386 represent human PKC antisense oligonucleotides used in the exemplification of the present invention. The antisense oligonucleotides are useful for the treatment of diseases associated with PKC expression, such as hyperproliferative and inflammatory conditions including psoriasis, tumours and cancer

                                                                                                                                                                                                                                                     This invention describes novel oligonucleotides (AAX78524-X78644) having up to 50 nucleotides hybridisable with, and able to modulate the expression of, a nucleic acid encoding protein kinase C and its isozymes alpha, beta type I, beta type II, gamma, eta, delta, epsilon and zeta. The oligonucleotides of the invention have anti-inflammatory and cytostatic activity and are used for antisense targeting to modulate the expression of PKC or of a particular PKC isozyme or set of isozymes in cells or tissues. The products of the invention also hybridise with nucleic acids involved in the modulation of PKC expression, which is known to be involved growth control in hyperproliferative diseases e.g. colon cancer, glioblastoma and bladder cancer as well as in inflammatory conditions e.g. psoriasis. Due to their specificity the oligonucleotides are able to overcome the problems of toxicity associated with previous agents designed to modulate PKC expression.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        14-JUN-1996;

                                                                                                                                                   The present invention describes a method of inhibiting the expression of chuman protein kinase C (PKC) in cells. The method comprises contacting the cells with an antisense oligonucleotide which has up to 50 nucleotide units. AAX83633 to AAX83720 represent specifically claimed artisense oligonucleotides for use in the method of the invention. The antisense oligonucleotides modulate hybridize to messenger RNA from the PKC gene which results in modulation of expression of the PKC gene. This means they can be used for diagnosis, therapeutic or prophylactic treatment of PKC associated diseases such as cancer and psoriasis, and as research agents. Abnormal proliferative states in tissue from patients suspected of having a hyperproliferative disease e.g. cancer, psoriasis can be diagnosed. Tumours associated with PKC can be genicated to allow an efficacious treatment regime to be used. The antisense oligonucleotides considered from tumours which are not PKC associated to allow an efficacious treatment regime to be used. The antisense oligonucleotides considered to activity so are able to modulate PKC activity without producing side effects and with greater effectiveness than observed content of the constraints of current agents. AAX83721 to AAX83753 represent over the constraints of current agents. AAX83721 to AAX83753 represent over the constraints of current agents. AAX83721 to AAX83753 represent over the constraints of current agents.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          This invention describes antisense oligonucleotides that specifically bind to human protein kinase C (PKC) mRNA. These oligonucleotides can be used to inhibit PKC mRNA and therefore be used to treat PKC-related hyperproliferative conditions, e.g. cancer, especially colorectal cancer, breast cancer, bladder cancer, lung cancer, or brain cancer (preferably glioblastoma multiforme). The products of the invention may also be used to treat skin cancer and psoriasis.

                                                                           of up to 50 nucleotides in length which specifically bind human protein calkingse C-alpha (PKC-alpha) mRNA. AAX1917 to AAX19247 represent cantisense oligonucleotides from the present invention which bind human PKC-alpha, -beta, -gamma, -delta, -epsilon, -zeta and -eta. The antisense oligonucleotides modulate the expression of the PKC gene (i.e. inhibit the PKC gene). The antisense oligonucleotides can be used to diagnose abnormal proliferative states in tissue or other samples from patients suspected of having a hyperproliferative disease e.g. cancer or psoriasis. The antisense oligonucleotides can be used to distinguish pKC-associated tumours and to detect and diagnose PKC expression (through the use of 32P labeled antisense oligonucleotides). Radiolabeled antisense oligonucleotides can also be used to perform autoradiography of tissues to determine the localization, distribution and quantitation of PKC expression for research, diagnostic and therapeutic purposes. The use of the antisense oligonucleotides eliminate the side effects associated with prior art methods because it modulates the amount of PKC protein
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  07-JUN-1995;

Best Local Similarity
Matches 17; Conserv The present sequence is that of a claimed enzymatic nucleic acid (i.e. a ribozyme) which cleaves ICAM-1 mRNA at the nucleotide base position indicated in the DE line.

Regions of the mRNA that do not form secondary folding structures and that contain potential hammerhead and hairpin ribozyme cleavage sites were identified by computer analysis. Ribozymes directed against these mRNA sequences were designed and synthesised with modifications that improve their nuclease resistance. The ribozymes cleave the ICAM-1 target sequences and thereby inhibit ICAM-1 expression, making them useful for reducing transplant rejection and alleviating symptoms in patients with rheumatoid arthritis, asthma and other inflammatory disorders. Ribozymes directed against these mRNA sequences were designed and synthesised with modifications that improve their nuclease resistance. The ribozymes cleave the ICAM-1 target sequences and thereby inhibit ICAM-1 expression, making them useful for reducing transplant rejection and alleviating symptoms in patients with rheumatoid arthritis; asthma and other inflammatory disorders.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Qy
                            cc performing a single-nucleotide primer extension reaction. The colligonucleotides are useful for determining the presence, absence or cc didentity of a SNP and for genotyping nucleic acid samples, for e.g. to assess by association analysis the genotype of an individual or group of cc didentity of a SNP and for genotypic traits include diseases e.g. caused by one or more SNPs. Phenotypic traits include diseases e.g. cc agammaglobulinaemia, diabetes insipidus, lesch Nyhan syndrome, muscular cc dystrophy, familial hypercholesterolaemia, polycystic kidney disease, cc dystrophy, familial hypercholesterolaemia, polycystic kidney disease, cc costeogenesis imperfecta and acute intermittent porphyria. Phenotypic traits also include symptoms of or susceptibility to multifactorial cc disease of which a component is or may be genetic such as autoimmune cd diseases, including, rheumatoid arthritis, multiple sclerosis, cc inflammation, cancer, nervous system diseases and infection by pathogenic microorganism. The method is also useful in forensic investigations and contentity analysis. The present sequence represents a fragment of human cannot a stories and acute of the present sequence represents a fragment of human cannot be sequenced.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Query Match

                                                                                                                                                                                                                                                                                                                               primer extension (SNPE) primers, and the sequences of regions flanking sites of single nucleotide polymorphisms SNPs. The present invention includes kits for determining the presence or absence of a SNP, using to oligonucleotides of the invention. The PCR primers are used to amplify SNP flanking sequence, the SNPE primer is used as a genotyping primer. The oligonucleotides are useful for genotyping a nucleic acid sample by
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       acid

exhibit improved wash performance in a detergent in comparison to its parent enzyme. The subtilase variant is used for the removal of egg stains from laundry or from hard surfaces, and in cleaning or detergent compositions, preferably a laundry and/or dishwash composition. The

present sequence represents a PCR primer which was subtilase variants of the invention.

The specification describes a subtilase variant, which comprises at least one additional amino acid residue in the active site loop region from position 95-103 (BASBPN numbering). Subtilases are serine proteases, which catalyse the hydrolysis of peptide bonds. Variants of subtilases which catalyse the hydrolysis of peptide bonds.

Use of a subtilase variant comprising acid residue in its active site loop,

at least one additional for removal of egg stai

                                                                                                                                                                                    The present invention describes antisense oligonucleotides up to 50 nucleotides in length which specifically bind mRNA encoding human protein kinase C (PKC). AAZ27266 to AAZ27366 represent human PKC antisense oligonucleotides used in the exemplification of the present invention. The antisense oligonucleotides are useful for the treatment of diseases associated with PKC expression, such as hyperproliferative and inflammatory conditions including psoriasis, tumours and cancer

                                                                                                                                                                                                                                  This invention describes novel oligonucleotides (AAX78524-X78644) having up to 50 nucleotides hybridisable with, and able to modulate the expression of, a nucleic acid encoding protein kinase C and its isozymes alpha, beta type I, beta type II, gamma, eta, delta, epsilon and zeta. The oligonucleotides of the invention have anti-inflammatory and cytostatic activity and are used for antisense targeting to modulate the expression of PKC or of a particular PKC isozyme or set of isozymes in cells or tissues. The products of the invention also hybridise with nucleic acids involved in the modulation of PKC expression, which is
                                                                                                                                                                        known to be involved growth control in hyperproliferative diseases e.g. colon cancer, glioblastoma and bladder cancer as well as in inflammatory conditions e.g. psoriasis. Due to their specificity the oligonucleotides are able to overcome the problems of toxicity associated with previous
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      PKC; human; PKC-alpha; primer; protein kinase C; expression modulator; PKC-beta type I; PKC-beta type II; PKC-gamma: PKC-eta; PKC-delta; PKC-epsilon; PKC-zeta; anti-inflammatory; cytostatic; antisense targeting; isozyme; growth control; hyperproliferative disease; colon cancer; glioblastoma; bladder cancer; inflammatory condition; psoriasis; ss.
